Abstract

The aim of this study is to explore parents' awareness of developmental learning difficulties among kindergarten children in the light of the two variables (sex and educational qualification). The study sample consisted of (20) Parent of children with developmental learning difficulties in Jubail city. The study follows a descriptive approach. To achieve the objectives of the study, a questionnaire developed by the researchers was used for measuring the awareness of parents. The study found that the awareness of kindergarten parents about developmental learning difficulties is higher than the average, and there are no statistically significant differences at the level of (0.05) or less between the sample regarding the sex and educational qualification. The study recommended providing workshops to increase the parents’ awareness about learning developmental.

Keywords: Awareness; Parents; Kindergarten children; Developmental learning Difficulties.

1. Introduction

In the past decades, interest in the field of special education has prevailed over certain forms of disabilities, such as mental, auditory, visual, and motor impairments. However, there is a group of children who have no apparent disability yet face some developmental and academic problems. This group of children does not reach enough attention leading to a significant deficit in one or more aspects of learning (Melhem, 2006). This deficit can be recognized through the academic achievements of children, which are often characterized by low levels (Mohammad, 2006), in Saudi Arabia, these children are referred to as having learning difficulties, which are divided into two types, academic and developmental. In this regard, learning difficulties in the
kindergarten stage appear in developmental learning skills, which are important and necessary for effective learning in the advanced grades.

Parents’ awareness of the manifestations of learning difficulties plays an important role in the success of the school intervention (Alsemari, 2016). However, some parents do not notice the developmental difficulties that their child faces in the kindergarten stage, and this often leads to academic difficulties. Developmental learning difficulties can be defined as “The difficulties that deal with the pre-school processes that are represented in the cognitive processes related to attention, perception, memory, thinking, and oral language, and these processes form the most important foundations on which an individual's cognitive mental activity is based. Therefore, any disorder or defect that affects one or more of These processes necessarily leads to more difficulties later, and these difficulties may appear in a child of school-going age” (Abu Diyar, 2012, p. 123).

Through the researchers practicing work in the kindergartens of the Royal Commission in Jubail, they noticed the unwillingness of parents to accept the development sessions for their children, or the lack of cooperation and participation, which may exacerbate the problems of later. Therefore, we seek through this study to identify the degree of parents’ awareness about the developmental learning difficulties that appear on their child and the relationship of this awareness to the parent’s gender and educational qualification. Specifically, the study attempted to answer the following research question:

RQ1: What is the degree of awareness of kindergarten parents about developmental learning difficulties?

This question can be broken into two sub-questions:

RQ2: Are there any differences between kindergarten parents' awareness according to the gender variable?

RQ3: Are there any differences between kindergarten parents' awareness according to the educational qualification variable?

2. Methodology

This study followed descriptive approach due to its relevance to the objectives of the research. descriptive approach aims to test hypotheses by collecting data (Al-Khalili, 2012).

2.2 Participants

Participants consisted of 20 parents of kindergarteners’ children with developmental learning difficulties attending early intervention programs in Jubail Industrial City. The sample was diverse included 7 different kindergartens (see table 1)

### 3.2 Characteristics of the participants

A number of main variables have been identified to describe the participants of this study, including gender and educational qualification which have indicative indicators of the results of the study. In addition, these variables reflect the educational background of the participants and help to lay the foundations on which the various analyzes related to the study see table (2).

### 4.2 Instrument

A questionnaire was developed following the Fathi Al-Zayat battery and the Michael Best scale. The questionnaire’s main domains are attention, memory and perception. The questionnaire consisted of (35) items in its initial form. The five-point Likert scale.
was used to obtain the responses of the study subjects, according to the following degrees of approval: (Strongly agree - agree – agree to some extent - disagree - strongly disagree). Each of the previous statements was giving a score, according to the following: Strongly agree (5) degrees, agree (4) degrees, agree to some extent (3) degrees, disagree (2) two degrees, strongly disagree (1) one score. In order to determine the length of the five Likert scale categories, the range was calculated by subtracting the upper bound from the lower bound (5–1 = 4), and then dividing it by the largest value on the scale (4 ÷ 5 = 0.80), and then was added This value is reduced to the lowest value on the scale (1); To determine the upper limit for this class. The length of the term was used to obtain an objective judgment on the averages of the responses of the study individuals, after treating them statistically. An electronic version of the questionnaire was developed using the Google Drive.

5.2 Construct Validity

Pearson's Correlation Coefficient was calculated; To identify the degree to which each of the questionnaire item is related to the total degree of the axis, as shown in Table (3):

| Table 3 Pearson correlation coefficients for axes phrases with overall score for each axis Table |

It is clear from Table No. (3) that the values of the correlation coefficient of each of the items with its axis are positive, and statistically significant at the level of (0.01) or less. This indicates the validity of the internal consistency between the items of the three axis and their relevance to measuring what they were supposed to measure.

6.2 Reliability

Reliability of the tool was confirmed by the use of the Cronbach's Alpha (α). Table (4) shows the values of the constant coefficients for each axis of the questionnaire.
Table (4) shows a high general constant coefficient, reaching (0.895), and this indicates that the questionnaire reliable and can be relied upon in the field work of the study.

7.2 Procedures

The researchers contacted the teachers of developmental learning difficulties in the Royal Commission Kindergarten in Jubail, in order to send the questionnaire...
electronically to the parents of children with developmental learning difficulties, and they followed up on the parents’ responses to the questionnaire, then collected the data and analyzed it statistically.

8.2 Data analysis

Data were analyzed statically using SPSS, and the following statistical measures were calculated:

1- Frequencies and percentages; to identify the characteristics of the study sample and determine their responses to the items of the main axes of the study tool.
2- Weighted Mean; this is to identify the average responses of the study sample to each of the items of the axes, and it was also useful for arranging the items according to the highest weighted mean.
3- Mean; This was to find out how high or low the responses of the study sample were from the main axes, and it helped arranging the axes according to the highest average.
4- Standard Deviation; to identify the extent of the responses’ deviation of the study sample to each of the items of the study variables, and for each of the main axes, from their mean. It is noticed that the standard deviation shows the dispersion in the responses of the study sample for each of the items. The more its value approaches zero, the responses are concentrated, and their dispersion decreases.
5- Mann-Whitney test to investigate the differences between the trends of the study sample according to their variables, which are divided into two categories.

3. Results and discussions

In this part, the researchers review the results of the statistical analysis of the research questions, their interpretation and discussion in light of the literature and previous studies.

The main question of this study is: What is the degree of awareness of kindergarten parents about developmental learning difficulties?

To answer this question, the mean of the tool’s dimensions was calculated to determine the degree of awareness of kindergarten parents of developmental learning difficulties in Jubail, as shown in Table (5):
It is clear from Table No. (5) that the degree of awareness of kindergarten parents about developmental learning difficulties in Jubail city is tending to rise, as the total of the dimensions (attention, perception, memory) came with a mean of (3.51) and a standard deviation (0.508), and the first dimension (attention) came with a mean of (3.73) and a standard deviation (0.586), followed by the second dimension (perception) with a mean of (3.50) and a standard deviation (0.554). Finally, the third dimension (memory) came with a mean of (3.29) and a standard deviation (0.595).

This result is based on the developmental theory, which explains the developmental learning difficulties, that human growth in general and the growth of the cognitive aspect in it, are subject to a sequential pattern of stages, in which the previous stage is paved for the next stage, and that each stage has its own characteristics in terms of function and structure, and there is an interactive relationship between the level of maturity and learning tasks for the individual (Suhail, 2012). The result of this study is in the line with the study of Al-Samari (2016) as the researcher found positive views in the learning difficulties programs represented in the effectiveness of the program, communication with parents and their participation in their child intervention program. The researchers explain this result from perceptual theory as Nasrallah and Mazal (2011) stated that students with learning difficulties face obstacles in perception, such as visual perception, auditory perception and haptic perception. The researchers believe that as parents can clearly notice the perception problems that their child faces through some behaviors such as failure to recognize and distinguish between images, or the inability to hold the pen, they search for the causes of the problem and thus raise their level of awareness. The researchers also attribute this result to the prevalence rate of attention deficit in children compared to other developmental difficulties. For example, Samara (2015) indicated that attention deficit is the most common among children, as
the number of people affected by it is about 5% of the total world population, so education authorities payed attention to this problem and provided parents with free workshops to raise their awareness toward attention deficit.

The second question of this study is: Are there any differences between kindergarten parents’ awareness according to the gender variable? To answer this question Mann-Whitney Test was used to clarify the significance of the differences between the participant’s responses according to the sex variable and the results came as shown in Table (6):

<table>
<thead>
<tr>
<th>Domain</th>
<th>Sex</th>
<th>Numbers</th>
<th>Mean</th>
<th>Total</th>

<td>4</td>
<td>13.25</td>
<td>53.00</td>
<td>21,000</td>
<td>0.298</td>
<td>No</td>
</tr>
</tbody>
</table>
It is clear from Table No. (6) that there are no statistically significant differences at the level of (0.05) or less in the average degrees of awareness of kindergarten parents about developmental learning difficulties in Jubail Industrial City, according to the difference in the gender variable. This result is partly consistent with the study of Al-Nusayri (2019), which showed that there were no statistically significant differences at the level of (α≤0.05) on learning difficulties teachers about the elements of the classroom environment according to the gender variable. The researchers attribute this result to the fact that the parent variable, whether male or female receives adequate care by Saudi Arabia through providing all support for the family and the child, and educational institutions are requested to improve their communication with the parents and enhance their role in the child learning process.

The third question of the study is: Are there any differences between kindergarten parents’ awareness according to the educational qualification variable?

To answer this question Mann-Whitney Test was used again to clarify the significance of the differences between the participant’s responses according to the educational qualification variable and the results came as shown in Table (7):

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

It is clear through the results shown in Table No. (7) that there are no statistically significant differences at the level of (0.05) or less in the attitudes of the study individuals regarding the difference in the educational qualification variable. This
question was based on the statement of Rafiqah (2014) as he referred to the role that the educational level of parents plays in developing their children's tendencies in a conscious and deliberate way, and its role on the child's academic achievement as they work in early age to provide rich learning environment that help their child acquire various learning skills. This result is in agreement with of Al-Baz and Petal (2016), where their study results showed that there were no statistically significant differences in the level of awareness of learning difficulties among kindergarten teachers according to the qualification variable. The researchers attribute this result to educational degree of most parents (Bachelor). This is maybe due to the support provide to all citizens through equality in learning opportunities as Saudi Arabia one of the countries that offers free education until university stage.

4. Conclusion

1- The awareness level of parents of kindergarten children regarding developmental learning difficulties is higher than the average with a statistically significant degree.
2- There are no statistically significant differences at the level of (0.05) or less in the attitudes of parents about (attention, perception, memory, awareness of parents of children with developmental learning difficulties among kindergarten children in Jubail Industrial City) according to the sex variable.
3- There are no statistically significant differences at the level of (0.05) or less in the attitudes of parents about (attention, perception, memory, and awareness of parents of children with developmental learning difficulties among kindergarten children in Jubail Industrial City) according to the educational qualification variable.

5. Research recommendations:

In light of the results obtained, the researchers recommended the following:

1- Providing awareness programs and workshops on developmental learning difficulties in Jubail, Kingdom of Saudi Arabia.
2- Working on removing the obstacles that limit the early detection of developmental learning difficulties in Jubail Governorate, Kingdom of Saudi Arabia.
3- Focusing on improving the knowledge and skills of mothers with developmental learning difficulties in Jubail Governorate, Saudi Arabia as mother’s role is significant in early childhood.
4- Including parents with higher education degree in the process of community awareness in developmental learning difficulties.
5.1 Future studies:

1- Conducting future studies on the effectiveness of awareness programs on developmental learning difficulties in kindergarten.
2- Conducting future studies on the role of educational institutions in raising awareness of developmental learning difficulties in the kindergarten stage
3- Conducting future studies on family needs regarding knowledge and skills to identify developmental learning difficulties in the early stage.
4- Conducting future studies on the effectiveness of training programs based on methods of teaching children with developmental learning difficulties.
